AB  - Successful training not only must involve overload but also must avoid
      combination of excessive overload plus inadequate recovery. Athletes ca
      experience short-term performance decrement without severe psychologica
      lasting other negative symptoms. This functional overreaching will even
      lead to an improvement in performance after recovery. When athletes do
      sufficiently respect the balance between training and recovery, nonfunc
      overreaching (NFOR) can occur. The distinction between NFOR and overtra
      syndrome (OTS) is very difficult and will depend on the clinical outcom
      exclusion diagnosis. The athlete will often show the same clinical, hor
      other signs and symptoms. A keyword in the recognition of OTS might be
      maladaptation" not only of the athlete but also of several biological,
      neurochemical, and hormonal regulation mechanisms. It is generally thou
      symptoms of OTS, such as fatigue, performance decline, and mood disturb
      more severe than those of NFOR. However, there is no scientific evidenc
      either confirm or refute this suggestion. One approach to understanding
      etiology of OTS involves the exclusion of organic diseases or infection
      factors such as dietary caloric restriction (negative energy balance) a
      insufficient carbohydrate and/or protein intake, iron deficiency, magne
      deficiency, allergies, and others together with identification of initi
      events or triggers. In this article, we provide the recent status of po
      markers for the detection of OTS. Currently, several markers (hormones,
      performance tests, psychological tests, and biochemical and immune mark
      used, but none of them meet all the criteria to make their use generall
      accepted.
